NOVELTY - Solid-phase oligonucleotide synthesis (M1) comprising capping the ends of a double stranded DNA (dsDNA) consisting of sense and antisense oligonucleotides, cleaving the dsDNA at or near a Watson-Crick base pair mismatch and digesting the uncapped dsDNA, is new.

DETAILED DESCRIPTION - Solid-phase oligonucleotide synthesis (M1) comprising:

(a) synthesizing a sense and an antisense oligonucleotide;

(b) annealing the sense and antisense oligonucleotides to form double stranded DNA (dsDNA);

(c) capping the ends of the dsDNA;

(d) cleaving the dsDNA, where **cleavage** occurs at or near a Watson-Crick base pair mismatch; and

(e) digesting the uncapped dsDNA, is new.

INDEPENDENT CLAIMS are also included for:

(1) forming long polynucleotides (M2) comprising:

(a) synthesizing a first proofread dsDNA by employing the steps of M1;

(b) synthesizing a second proofread dsDNA; and

(c) ligating the first proofread DNA with the second proofread DNA to form a long polynucleotide;

(2) an apparatus for performing M1; and

(3) an apparatus for performing M2.

USE - M1 is useful for synthesizing high-fidelity oligonucleotides (claimed), which may be used as probes, or in medical diagnostics, life sciences, and the pharmaceutical industry. The sequences produced may be used as synthetic genes and synthetic chromosomes to direct protein synthesis in living systems, or for information storage in devices such as molecular computers.

ADVANTAGE - M1 is used to synthesize high purity short oligonucleotides with fewer errors and eliminates the need for inefficient HPLC or other cleanup.

AB The core 2-type tetrasaccharide building blocks (1a/1b) for **solid -phase synthesis** of glycopeptide were synthesized via stereaselective glycosylation of the disaccharyl Ser/Thr (3a/3b) with a glycosyl fluoride (2) carrying the 2-trichloroacetamido group that was readily converted into a 2-acetamido group by reduction. A segment of glycoprotein leukosialin (215-224) was synthesized by the solid-phase protocol, the building block (1b) being utilized. **Cleavage** of the synthetic glycopeptide from resin was effected with reagent K and subsequent treatment of the product with a cocktail for the 'low-acidity

TfOH' facilitated complete removal of the benzyl groups with minimum loss of glycosidic linkages. To the deprotected glycopeptide (21), were enzymatically introduced N-acetylneuraminic acid (sialic acid) residues in remarkably high efficiency by using the specific sialyltransferases.

AB A method for the preparation and encoding of readily deconvoluted combinatorial libraries is discussed. Beads are prepared with topol. segregated regions - an inner region to which is bound coding tags and an outer segment to which the library compound is bound. Coding blocks are attached to the inner resin by a **cleavable** methionine-containing linker; the coding blocks are chosen to have similar reactivities to the building blocks incorporated in the synthesis of the combinatorial library. Synthesis of the library leads to the functionalization of the library-containing portion of the resin bead and the coding portion of the resin bead. **Cleavage** of the linkers for the coding blocks from the resin bead by Edman degradation with cyanogen bromide yields lactones whose mass is determined by FT-**MALDI** mass spectroscopy. Anal. of the lactones isolated from a given bead yields the mass of each of the fragments present; by careful choice of coding blocks and reactants, the identities of the building blocks incorporated into a library bead and of the library member attached to that bead can be readily derived from the fragment masses. A combinatorial library is prepared and tested for the binding of library members to streptavidin; seventeen of the compds. are found to bind strongly to streptavidin by a colorometric assay and identified unambiguously by the library encoding method described here.

ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS
AB Undesired N-7 platination of 2'-deoxyguanosine residues at predetermined sites in an oligodeoxynucleotide (ODN) sequence is prevented by applying the sterically demanding diphenylcarbamoyl (DPC) as an

O-6-protecting group. The presence of a base-labile oxalyl linker between the immobilized 3'-nucleotide and controlled pore glass (CPG) allows **cleavage** of the protected ODN from the support and leaves DPC protection unaffected. This method provides an ODN with specifically blocked guanine-N-7 sites for platination. In the hexanucleotides prepared in this study, 5'-GGBGGT-3'(for B = T, C and A), a platinum GG adduct is introduced at G4,G5. These site-specific platinated hexamers were isolated in a yield of 65%, and were fully characterized by using reversed-phase HPLC (high performance liquid chromotography), LCMS (liquid chromatography-mass spectrometry), **MALDI**-TOF MS (matrix-assisted laser desorption/**ionization** time-of-flight mass spectrometry), PAGE (polyacrylamide gel electrophoresis) and Maxam-Gilbert sequencing analysis.

AB Potentially biol.-active nanostructures can be created from single chains of unmodified peptides by crosslinking different regions of the chain by disulfide bonds and cleaving the chain at specified sites to obtain the final configuration. The availability of techniques for assembly and characterization of such structures was tested on a two-loop structure created from a 21-residue linear peptide. Directed intra-mol. disulfide bond formation was performed by inserting partial sequences favoring intra-mol. S-S bond formation ("loops") separated by partial sequences disfavoring such a process ("spacers") into the precursor sequence. Peptide bond **cleavage** by partial acid hydrolysis at specific sites (GG, NP/DP) inside the loops opened them; the same process in the spacer separated the loops. Synthesis, oxidation and bond **cleavage** were monitored by matrix-assisted laser desorption/**ionization** time-of-flight mass spectrometry (**MALDI** ToF MS). The hydrolysis fragments of the produced nanostructures were characterized by tandem electrospray **ionization** Fourier transform mass spectrometry (ESI FT-MS) with collisional and electron capture dissocns. The latter technique was especially useful as it cleaves S-S bonds preferentially. The feasibility of the proposed synthesis approach and the adequacy of the anal. techniques for the test structure were demonstrated.

AB A synthetic strategy for the preparation of side chain free (deprotected) peptides on biocompatible solid supports is described. Final peptide detachment is afforded in mild basic conditions with no presence of scavengers or other additives, thus allowing single peptide-resin beads to be **cleaved** in mass spectrometry sample plates for direct sequencing using **MALDI**-TOF post-source decay. Using a [9-(hydroxymethyl)-9H-fluoren-2-yl]-carbamic acid moiety (I) as bifunctional linker, **cleavable** under mild basic conditions (morpholine in DMF), the final **cleavage** can be accomplished directly on **MALDI** plates to ensure no losses of pos. compds. This methodol. offers clear advantages for the development of one-bead-one-compound combinatorial libraries in addition to parallel and regular synthesis of peptides.

AB Oligonucleotides containing 7-(omega-aminoalkyn-1-yl)-7-deaza-2'-deoxyguanosines (1a-c) were investigated regarding their thermal stability (T(m) values) as well as their phosphodiester hydrolysis catalyzed by exonucleases. Those derivatives are suitable for the labeling of nucleic acid constituents as well as for the postlabeling of DNA. For this, the phosphoramidites 7a,c (obtained from the nucleoside 1a,b), protected by an isobutyryl group at the 2-amino group and a phthaloyl residue at the side-chain amino function, were synthesized. Using compounds 7a,c together with the phosphoramidite of 1c in **solid-phase synthesis**, a series of self-complementary and non-self-complementary oligonucleotides were prepared and characterized by **MALDI**-TOF mass spectrometry. A comparison of the T(m) values of the modified oligomers shows that the thermal stability of the duplexes

decreases with the length of the nucleobase 7-(omega-aminoalkyn-1-yl) side chain. Exonucleolytic **cleavage** of oligonucleotide single strands incorporating either the 7-(3-aminopropyn-1-yl)- or the 7-(4-aminobutyn-1-yl)-substituted nucleosides 1a or 1b, respectively, reveals that 3' --> 5' specific snake venom phosphodiesterase liberates 1a 5'-monophosphate but not the methylene-extended 1b 5'-monophosphate. On the contrary, the 5' --> 3' specific bovine spleen exonuclease is able to **cleave** off single 1a and 1b 3'-monophosphate residues; its action is, however, terminated in the case of oligonucleotides containing two consecutive 1a or 1b nucleotide units.

AB The increasing demand for short- and medium-sized peptides in many fields of biol., medical and pharmaceutical research requires optimized and universally applicable high-throughput synthesis and purification techniques at the low-μmol scale. Here, we describe a continuous peptide synthesis/purification approach using the 96-well format. First, a μmol scale peptide synthesis on resin beads was optimized on a novel miniaturized 96-reaction vessel block employing standard Fmoc/tBu-chemical Almost 90% of the synthesized peptides contained the target sequence as the main component, as judged from matrix-assisted laser desorption/ **ionization** (**MALDI**) mass spectra. Impurities were mostly related to partially protected peptides. Second, we tested the applicability of ion pair reversed-phase solid-phase extraction (IP-RP-SPE) to purify individual peptides. Depending on the length and predicted hydrophobicity of the peptides, elution was performed with 25 or 35% aqueous acetonitrile in the presence of 0.1% trifluoroacetic acid (TFA). Thus, scavengers used during TFA **cleavage** and partially protected peptides carrying very hydrophobic protecting groups were effectively removed. Using a narrow step gradient, the target peptides were even separated from deleted sequences and protected peptides with similar hydrophobicities. Third, we combined the μmol-scale synthesis in the 96-well format with purification by IP-RP-SPE on a 96-well micro-extraction plate format. This simple, fast and parallel approach was tested on 12-mer and 15-mer peptides to map epitopes of T- and B-cell clones, resp. Approx. 80% of all peptides were obtained at purities >90% without purification by RP-HPLC. In summary, this novel approach has several advantages: (i) the μmol-scale reduced the cost of peptide synthesis, (ii) large nos. of peptides were purified faster, (iii) the vols. of eluents and waste were significantly reduced, and (iv) the RP-HPLC column was not contaminated with hydrophobic impurities.

OS CASREACT 135:195741
AB The insertion of the (5R*) and (5S*) diastereoisomers of 1-[2-deoxy-β-D-erythro-pentofuranosyl]-5-hydroxyhydantoin- a major oxidation product of 2'-deoxycytidine upon exposure to OH radicals, excited photosensitizers, or ozone - into oligonucleotides is reported. It was achieved by means of phosphoramidite chemical, using the **solid-phase synthesis** approach. The synthesis of the phosphoramidite synthon required 6 steps from 3'-O-(tert-butyldimethylsilyl)-2'-deoxycytidine and involved protection of the secondary hydroxy group (5-OH) of the modified base by the nonstandard levulinyl group. This modified phosphoramidite synthon was efficiently incorporated into several oligonucleotides (3-mer, 14-mer, 22-mer) by solid-support assembling. The presence and the integrity of the (5R*) and (5S*) diastereoisomers of 1-[2-deoxy-β-D-erythro-pentofuranosyl]-5-hydroxyhydantoin in the synthetic oligomers was confirmed by electrospray **ionization** mass spectrometry, together with HPLC and **MALDI**-TOF mass-spectrometric analyses of enzymic digestions. The use of exonucleases (calf spleen phosphodiesterase and bovine intestinal mucosa phosphodiesterase) clearly showed that enzymic hydrolysis of the phosphodiester bonds between the (5R*) and (5S*) diastereoisomers of 1-[2-deoxy-β-D-erythro-pentofuranosyl]-5-hydroxyhydantoin and normal 2'-deoxyribonucleosides is prevented, while endonuclease (nuclease P1) is able to **cleave** the lesion residue from the oligonucleotides.

AB This article illustrates the successful and efficient solid phase assembly of hydrophobic difficult sequence peptides following both t-Boc and Fmoc chemistry. The peptides were synthesized on an optimized 1,4-butanediol dimethacrylate-crosslinked polystyrene support (BDDMA-PS). Four difficult sequence test peptides, VAVAG, VIVIG, QVGQVELG and VQAAIDYING, were synthesized in relatively good yield and purity without any aggregation problems. The peptides were assembled on chloromethylated and 4-hydroxymethylphenoxymethyl (HMP) BDDMA-PS resins. The peptides were fabricated using Boc amino acid 1-hydroxybenzotriazolyl and Fmoc amino acid pentafluorophenyl active esters in coupling reactions. The peptides after synthesis were **cleaved** from the polymeric support by exposing the peptidyl resin to 90% trifluroacetic acid/5% thioanisole/5%

EDT mixture. The HPLC and **MALDI** TOF MS studies of the peptides revealed the high homogeneity of the synthesized peptides. Chloromethylated resin having a functional group loading of 1.14 mmol Cl/g was used for the synthesis. The yield and homogeneity of these peptides synthesized using the new support were high when compared with the conventional DVB-PS resin.

AB A review. **Solid phase synthesis** is now widely recognized as the edge technol. for rapid and efficient oligosaccharide construction. However, it has several disadvantages which should be overcome, (i) the reduced reactivity of substrates, (ii) the difficulty of teal-time reaction monitoring, (iii) limitations on ability of scale-up reactions, and (iv) purification of the desired compds. We choose the PEG (Ave M. W. 550) as a polymer support. It gives homogeneous conditions in reaction mixture, so the reactivity of substrate bound to PEG does not diminished. The scale up of the reaction is possible because the low mol. weight of PEG. Due to its high polarity of PEG, purification of PEG bound sugar was quite simple using silica gel column chromatog. Using the nitro group introduced linker, which is quite stable under typical glycosylation reactions, the oligosaccharide was synthesized on PEG. The monitoring of the glycosylation reaction was performed by **MALDI** -TOF MAS based on the characteristic signal pattern which derives from normal distribution of PEG chain length. The reaction monitoring of deprotection of chloroacetyl group was performed by colorimetric assay by use of (p-nitrobenzyl)pyridine. Chloroacetyl group was selectively reacts with (p-nitrobenzyl)pyridine to give red color under basic conditions. The reaction was semi-quantified by use of NIH Image software. "Catch and release strategy" for the purification of polymer supported oligosaccharide was developed. Solid phase bound cysteine captures the glycosylated product having the chloroacetyl group. **Cleavage** reaction of Fmoc group releases the sugar via intramol. cyclization process into the solution phase. By repetition of glycosylation/capture/release cycle, the poly(lactosamine) was synthesized on polymer support.

AB Preparation of fully protected peptide C-terminal esters in high yield and purity by making use of gel-phase synthesis on chloromethyl butanediol dimethacrylate (BDODMA) crosslinked polystyrene is described. The C-terminal amino acid of the peptide was incorporated by cesium salt

method and the step-wise synthesis was carried out using HOBt active ester coupling procedure. The protected peptides were **cleaved** from the support by trans-esterification. The crude peptides were purified by HPLC and characterized by amino acid anal., tlc and **MALDI** TOF MS.

AB High quality purification of membrane-spanning peptides and proteins remains a challenging problem. In this work we describe a tailored chromatographic purification of a synthetic 35-residue peptide corresponding to the transmembrane region of the tyrosine kinase receptor c-erb2/neu. Composed to over 70% by the amino acids alanine, isoleucine, leucine, phenylalanine and valine, this peptide presents a very hydrophobic character. Product isolation from the complex peptide mixture, obtained after acid **cleavage** of the resin matrix used during the **solid-phase synthesis**, represents a difficult task. We propose a three step strategy based on gel permeation and reversed-phase high-performance liquid chromatography, using aprotic polar solvent mixtures. The challenge consisted in obtaining a sufficient amount of an extremely pure sample, in order to allow structural analysis by NMR spectroscopy. Keeping trace of the synthetic peptide throughout the different purification steps was assured by **MALDI** TOF mass spectrometry, and the final product purity was checked by coupled liquid chromatography-ESI TOF mass spectrometry.

AB The synthesis of defined arrays of peptide analogs in conjunction with a simple self-encoded chemical readout system provides a powerful method for the systematic investigation of the relationship between peptide mol. structure and function. A novel **solid-phase synthesis** procedure was used to prepare arrays of peptide analogs in which a specific thioester modification was systematically incorporated into a unique position in a peptide sequence. The synthesis was carried out in such a way that the resulting arrays contained a defined family of modified peptides, with each peptide mol. containing only a single specific modification. The array of peptide analogs was self-encoded in a positional fashion by incorporating a selectively **cleavable** thioester bond into the analog structure. Following **cleavage** of the peptide analog array, anal. of the resulting peptide fragments by **MALDI** mass spectrometry defined, in a single step, the presence and identity of each peptide analog in the mixture The feasibility of this approach was demonstrated by the synthesis and mass spectrometric readout of an array of 9 analogs of the 58-residue polypeptide chain of the cCrk N-terminal SH3 domain, before and after folding and affinity selection.

AB A method to use matrix-assisted laser desorption/**ionization** mass spectrometry (**MALDI**-MS) for real-time monitoring of organic reactions on polymeric supports used in **solid-phase synthesis** is described. The strategy utilizes a synthetic construct that allows for the rapid and convenient direct **MALDI** analysis of the attached substrates as well as their subsequent chemical **cleavage** as desired. We have used this strategy to monitor nucleophilic substitutions, palladium-catalyzed coupling reactions, and solid phase peptide synthesis reactions using both Boc- and Fmoc-based chemistries.

AB A simple yet highly effective application of matrix-assisted laser desorption/**ionization** mass spectrometry (**MALDI**-MS) for the rapid monitoring of 9-fluorenylmethoxycarbonyl (Fmoc) solid-phase peptide synthesis is described. A few beads of the resin are removed at any desired step during synthesis, the fully protected peptide is **cleaved** from the resin and an MS spectrum of the analytes present is produced. Some standard side-chain protecting groups may be **cleaved** off during sample preparation for MS anal.; however, these cleavages are readily identified. Using this approach, incomplete amino acid acylations are readily detected in approx. the same time as by traditional tests such as ninhydrin. The semi-online method also lends itself to ready optimization of synthesis protocols and to the examination of resin-bound peptide side reactions which may not be detectable by chemical means.

AB A dual linker analytical construct based on a photolabile carbamate is described. Photochemical cleavage from the solid support can be effected to afford an analytical fragment, containing the substrate, which is sensitised to electrospray mass **spectrometry**. We believe this simple construct now renders all substrates visible to high throughput mass specroscopic analysis.

AB Anal. construct technol. was successfully applied to the single-bead anal. of a split-mix combinatorial library. Substrates can be released from the resin by conventional cleavage for biol. screening. Alternatively, for the purpose of anal. and quality control, cleavage at an orthogonal construct linker produces an anal. fragment incorporating the substrate. This anal. fragment is highly sensitized to electrospray mass **spectrometry** (ESI-MS) and is easily identified by isotope labeling. The construct cleavage rendered readily visible even those compds. that clearly could not be seen by conventional cleavage and mass **spectrometry** anal. A 1H NMR control experiment proved that the compds. cleaved conventionally were, however, present in the sample in good yield

and purity. In view of the data obtained, the authors think that this is a significant and important step toward solving the authors' current quality control problems.

AB Protein tyrosine phosphatases regulate signal transduction pathways involving tyrosine phosphorylation and have been implicated in the development of cancer, diabetes, rheumatoid arthritis and hypertension. Increasing evidence suggests that the cellular redox state is involved in regulating tyrosine phosphatase activity through the reversible oxidization of the catalytic cysteine to sulphenic acid (Cys-SOH). But how further oxidation to the irreversible sulphinic (Cys-SO2H) and sulphonic (Cys-SO3H) forms is prevented remains unclear. Here we report the crystal structures of the regulatory sulphenic and irreversible sulphinic and sulphonic acids of protein tyrosine phosphatase 1B (PTP1B), an important enzyme in the negative regulation of the insulin receptor and a therapeutic target in type II diabetes and obesity. We also identify a sulphenyl-amide species that is formed through oxidation of its catalytic cysteine. Formation of the sulphenyl-amide causes large changes in the PTP1B active site, which are reversible by reduction with the cellular reducing agent glutathione. The sulphenyl-amide is a protective intermediate in the oxidative inhibition of PTP1B. In addition, it may facilitate reactivation of PTP1B by biological thiols and signal a unique state of the protein.

AB Conventional bioassay-based screening remains a mainstream approach for lead discovery. However, its limitations have meant that other, more biophysical methods, such as X-ray crystallography and NMR, are now being

developed as lead discovery tools. These methods are particularly effective at detecting the binding of low affinity, low molecular weight compounds and transforming them into novel potent leads using structure-guided chemistry. Here, we describe some of the technologies and approaches that are being developed in structure-based screening using X-ray crystallography, which promise to have a major impact on lead discovery.

AB A review. Conventional structure-based drug discovery routinely involves the use of crystal structures of target proteins; optimization of lead compds. uses three-dimensional information about the protein's binding site. Traditionally, x-ray crystallog. has been regarded as a very resource-intensive technique, which has restricted its use primarily to the lead optimization phase, where it is used to study a small number of high-value compds. However, as a result of major technol. advances in both software and hardware, rapid determination of protein and protein-ligand structures is now allowing x-ray crystallog. to be used in lead screening.

AB Solid phase synthesis and methods of anal. of the products are given. More specifically "a chemical construct for use in solid phase synthesis comprising a solid support Q having linked thereto via a connecting group Y a substrate R; the connecting group Y having first and second cleavage sites which are orthogonally and selectively cleavable; the second cleavage site being selectively cleavable to release the substrate; and the first cleavage site being located at a position between the second cleavage site and the solid support and being selectively cleavable to release a fragment Fru comprising the substrate and at least a portion of the connecting group Y, wherein the said portion contains a chromophore Cu which facilitates anal. of the fragment Fru by UV, visible or fluorescence spectroscopy, the chromophore Cu having a principal log Emax value of at least 2.5 and wherein (i) the principal log Emax value is at least 1.5 times greater than the principal log Emax of the substrate R; or (ii) the chromophore Cu has an absorption peak at a wavelength remote from absorptions due to the substrate R; and to methods of anal. of products of solid phase synthesis using the constructs". E.g., anthracenes I (X = H, D; R = 3-dimethylaminophenyl, 2-naphthylmethyl, 3-butenyl, tert-butylmethyl) were prepared by solid phase synthesis and analyzed by by UV.

AB Anal. construct technol. was successfully applied to the single-bead anal. of a split-mix combinatorial library. Substrates can be released from the resin by conventional cleavage for biol. screening. Alternatively, for the purpose of anal. and quality control, cleavage at an orthogonal

construct linker produces an anal. fragment incorporating the substrate. This anal. fragment is highly sensitized to electrospray mass spectrometry (ESI-MS) and is easily identified by isotope labeling. The construct cleavage rendered readily visible even those compds. that clearly could not be seen by conventional cleavage and mass spectrometry anal. A 1H NMR control experiment proved that the compds. cleaved conventionally were, however, present in the sample in good yield and purity. In view of the data obtained, the authors think that this is a significant and important step toward solving the authors' current quality control problems.

AB An anal. construct resin, designed to aid the anal. of solid-phase chemical, has been mixed in a small proportion with a conventional resin. The anal. construct ("reporter resin") contains two orthogonal linkers that allow cleavage of either the synthetic intermediates (at linker 2) or their anal. enhanced derivs. (at linker 1). The convenient and rapid monitoring of each step in the syntheses of representative library compds. was possible using small resin aliquots.
